Of the drugs available for attention-deficit hyperactivity disorder (ADHD), the most effective and safe for short-term treatment is methylphenidate for children, and amphetamines for adults, according to the most comprehensive evidence yet from a network meta-analysis and systematic review comparing the effectiveness and safety of seven ADHD drugs against placebo, published in The Lancet Psychiatry. The study compared the effectiveness and side effects of amphetamines (including lisdexamfetamine), atomoxetine, bupropion, clonidine, guanfacine, methylphenidate, and modafinil with each other or with placebo over 12 weeks of treatment. ADHD is estimated to affect 5% of school-age children and 2.5% of adults worldwide. The disorder is characterized by age-inappropriate levels of inattention, hyperactivity or impulsivity, or all of these. ADHD medications are not a permanent cure for ADHD but may help patients concentrate better, be less impulsive, feel calmer, and learn and practice new skills. Treatment breaks are occasionally recommended to assess whether the medication is still needed, but treatment for ADHD can be taken for periods longer than 12 weeks.

Half as many women in labor who were given a drug called remifentanil to help manage their pain needed a subsequent epidural, compared to the women given pethidine-the current standard of care, according to an open-label randomized controlled trial of 400 women published in The Lancet. Epidurals-injections of pain relief drugs around the spinal cordprovide effective pain relief but increase the risk of needing instrumental delivery (forceps or vacuum) during birth, which in turn can increase the risk of trauma and long-lasting problems for the mother, such as incontinence and sexual dysfunction.
